**Conditions Report**

*Karenia brevis* (commonly known as Texas red tide) ranges from not present to very low concentrations along the coast of Texas. Respiratory irritation and dead fish have been reported from the Padre Island National Seashore region and continued respiratory irritation may be possible Tuesday, September 6 through Monday, September 12. Our forecast will be updated if field samples confirm elevated concentrations of *K. brevis* along the coast this week. *K. brevis* concentrations are patchy in nature and levels of respiratory irritation will vary locally based upon nearby bloom concentrations, ocean currents, and wind speed and direction.

Check [http://tidesandcurrents.noaa.gov/hab/beach_conditions.html](http://tidesandcurrents.noaa.gov/hab/beach_conditions.html) for recent, local observations.

**Analysis**

Respiratory irritation and dead fish have been reported from mile marker 19 in the Padre Island National Seashore region, and water samples are being collected today (TPWD; 9/6). Elsewhere along the Texas coast, *Karenia brevis* ranges from background to ‘very low’ concentrations. Sampling from the Texas A&M University’s Imaging FlowCytobot, located on the Port Aransas ship channel, indicates that *K. brevis* ranges between ‘not present’ and ‘very low’ concentrations (TAMU; 8/29-9/6). Coastal samples collected from the Rio Grande Valley area indicated *K. brevis* ranges between ‘not present’ and ‘very low’ concentrations (TPWD; 8/29-9/2). All other samples collected last week along the Texas coast and in the bay regions indicated that no more than background concentrations of *K. brevis* are present (TPWD; 8/29-9/2). For information on area shellfish restrictions, contact the Texas Department of State Health Services.

Recent MODIS Aqua imagery (9/5; shown left) is partially obscured by clouds along the Texas coast from Sabine Pass to the Rio Grande, limiting analysis. Patches of elevated to very high chlorophyll (2 to >20µg/L) are visible along- and offshore from the Sabine Pass to Padre Island National Seashore regions. Elevated chlorophyll is not necessarily indicative of the presence of *K. brevis* and may be due to the resuspension of benthic chlorophyll and sediments along the coast.

Forecast models based on predicted near-surface currents indicate a maximum transport of 10 km north from the Port Aransas region and 30 km north from PINS Mile Marker #15 from September 5-9.

Kavanaugh, Lalime
Wind Analysis

**Port Aransas to Matagorda Ship Channel:** Southeast winds (10-20kn, 5-10m/s) today through Wednesday. South winds (10-15kn, 5-8m/s) Wednesday night to Thursday becoming southeast winds (5-15kn, 3-8m/s) Thursday night through Saturday night.
Satellite chlorophyll image and forecast winds for September 7, 2016 12Z with points representing cell concentration sampling data from August 27 to September 6: red (high), orange (medium), yellow (low b), brown (low a), blue (very low b), purple (very low a), pink (present), and green (not present). Cell count data are provided by Texas Parks and Wildlife Department. For a list of sample providers and a key to the cell concentration categories, please see the HAB-OFS bulletin guide:
http://tidesandcurrents.noaa.gov/hab/hab_publication/habfs_bulletin_guide.pdf

Verified and suspected HAB areas shown in red. Other areas of high chlorophyll concentration shown in yellow (see p. 1 analysis for interpretation).
